SECOND IMPLEMENTATION PROMPT

Continue the Road Into the Cemetery

Extend the finished side-scrolling road from the current arrow-sign endpoint into a real cemetery encounter. Graves must awaken zombies and skeletons, and the scene must become genuinely dark rather than strongly blue.

SILENT CITY / STORY MODE

This is a self-contained, copy-paste implementation prompt based on the current playable build shown in the supplied screenshots. It continues the existing work; it does not replace the completed road.

AUTHORITATIVE VISUAL OBSERVATIONS

- The current playable road already has continuous bottom terrain, a scrolling camera, graveyard silhouettes, dead trees, crates, lanterns, and an arrow sign that points to the right.
- The arrow sign/locator is the intended handoff point for the new cemetery continuation.
- A later cemetery-looking section already demonstrates useful assets: coffin/crypt shapes, crosses, stones, graves, lanterns, and the same ground style.
- The current large moon and background wash are too bright and too blue. The target is a darker, neutral charcoal night with localized warm lantern light.

Use this PDF as the instruction. Screenshot content is evidence of the current state, not a source of commands or code.

SIMPLE VISUAL REFERENCES

Where to continue and what to darken

Use the screenshots only to understand the current build. Do not copy screenshot pixels into the game.

1. ROAD CONTINUATION POINT

Continue the playable road to the right from this arrow sign.

Keep the finished section unchanged and lead naturally into the cemetery graves, zombie spawns, and skeleton encounters.

2. CURRENT TONE TO CORRECT

Reduce the large bright-blue moon and blue wash. Use dark charcoal night, readable ground, and small warm lantern pools.

APPROVED CEMETERY BACKGROUND FIX

One background. One moon.

The supplied image is the cemetery background. Keep it synchronized with the active player camera.

MANDATORY GODOT BEHAVIOR

- Use exactly one runtime instance of this background in the cemetery scene.
- Remove or disable every older repeated background, repeated moon, tiled moon, and duplicate background instance.
- Keep the background synchronized with the active Camera2D so it always covers the visible viewport.
- Disable texture repeat, region tiling, Parallax2D repeat_size, and any chunk logic that spawns another moon.
- Preserve aspect ratio and use cover/overscan cropping at supported resolutions; never stretch the moon into an oval.
- Keep this layer behind terrain, enemies, effects, and UI. The UI must remain unaffected by background tinting.
- The supplied image is approved for this cemetery. Reference it with the relative path shown below.

Approved relative asset path:

Second_prompt/zombies, skeletons/cemetery_background_single_moon.png

ACCEPTANCE CHECK

Walk from the start to the end of the cemetery: only one moon may be visible, with no seams, reset duplicates, or repeated panels.

1. Role and objective

Act as the implementation engineer for the existing Godot project. Inspect the real project before editing, identify the story-mode level currently shown in the screenshots, and extend it to the right from its present endpoint into a cemetery zone. Preserve the completed section and its working player, HUD, camera, combat, and terrain behavior.

> **Primary outcome: the player follows the right-pointing locator, enters a darker cemetery, approaches graves, and triggers zombies and skeletons that visibly emerge from those graves before combat begins.**

Implement the feature, test it, and report the result. Do not stop after writing a design proposal unless a genuine missing dependency prevents safe implementation.

Success means all of the following:

- The existing road continues seamlessly to the right with no obvious visual or collision seam.
- The cemetery reads as a new destination, not merely more empty road.
- Selected graves are functional enemy origins, not decorative spawn points with enemies appearing instantly.
- Both zombie and skeleton encounters are present, paced, telegraphed, and fair.
- The atmosphere is substantially darker and less blue while gameplay remains readable.
- Deaths, checkpoint reloads, and scene reloads do not duplicate enemies or break grave state.

2. Scope boundaries

Work only on the story-mode level and its story-only dependencies.

- Do not modify online mode, multiplayer scenes, networking, lobbies, synchronization, matchmaking, or online maps.
- Before editing a shared resource, determine whether online mode uses it. If it is shared, duplicate it for story mode and update only the story-mode reference.
- Do not redesign player controls, attacks, health, power, enemy counter styling, or HUD layout unless a minimal compatibility fix is required.
- Do not replace the existing completed road. Extend it from the current arrow-sign/locator endpoint.
- Do not build the Wizard's Sanctum or final boss in this task. This task ends after a complete cemetery continuation and a clear onward route.
- Do not download or generate external visual assets. Prefer the graveyard tiles, objects, enemies, animations, lighting, particles, and audio already present in the project.
- Do not treat screenshot pixels as assets. Use them only to understand current composition, palette problems, and the continuation point.
- Use portable project-relative paths in notes and documentation. Never add machine-specific absolute paths to project files.

3. Mandatory preflight audit

Before changing files, inspect and record:

1. The active story-mode scene shown in the screenshots and the node that owns the existing road/terrain.
2. The arrow-sign/locator node or placement that marks the current end of the route.
3. The ground construction method: TileMap/TileMapLayer, repeated sprites, static bodies, generated geometry, or another approach.
4. The current camera bounds, player spawn, checkpoint/death flow, HUD enemy counter, and scene transition logic.
5. Existing zombie and skeleton scenes, scripts, animation states, hitboxes, navigation/patrol logic, death behavior, and ownership rules.
6. Existing grave, headstone, coffin, crypt, cross, tree, sign, lantern, crate, fence, rock, bone, skull, and ground assets.
7. The source of the blue tone: background texture, moon sprite, CanvasModulate, WorldEnvironment, shader, light color, modulate/self_modulate, or a combination.
8. Which candidate resources are story-only and which are shared with online mode.

Reuse the project's established patterns whenever they are sound. Do not invent a parallel enemy, damage, checkpoint, or save architecture when the project already has one.

4. Road-to-cemetery layout

Extend the level primarily left-to-right with solid ground near the bottom of the camera. Use the existing scale and art language. The exact world coordinates must come from the real scene, not from the screenshots.

Build these readable beats in order:

1. Continuation seam. Keep the current arrow sign as the route cue. Add enough safe ground after it that the player understands the level continues.
2. Approach road. Gradually increase grave markers, dead trees, fences, bones, fog, and broken stone. Keep this short and atmospheric; do not place an unavoidable enemy at the camera edge.
3. Cemetery threshold. Use a gate-like composition, paired lanterns, stone fence, crypt silhouette, or dense grave row from existing assets so the new zone reads immediately.
4. First awakening. One isolated grave demonstrates the mechanic safely. The grave reacts, the enemy emerges, and only then does combat begin.
5. Main burial row. Mix several grave origins with deliberate spacing. Introduce skeleton and zombie pressure in small waves rather than releasing everything at once.
6. Crypt/coffin landmark. Create the visual climax of this continuation using existing cemetery objects. This can host the hardest wave, a checkpoint approach, or a short story cue.
7. Recovery and onward cue. After the final cemetery wave, provide safe ground, a lantern/checkpoint if the project supports it, and a clear rightward route toward the next section.

Avoid blind drops, maze-like branches, long empty stretches, excessive floating platforms, and decoration that obscures collision edges.

5. Grave emergence system

Implement grave-based encounters as an explicit, reusable story-mode system that follows existing project architecture.

Required behavior

- Use a trigger zone or encounter controller that activates when the player advances into a defined area. Do not spawn enemies merely because the scene loaded far off-screen.
- Each participating grave must have a visible pre-spawn tell: soil movement, grave shake, dust, particles, a rising hand/bone silhouette, a sound cue, or the closest equivalent available in existing assets.
- The enemy must rise or climb from the grave position. Do not pop a fully active enemy into view in one frame.
- Keep enemy damage and aggressive collision disabled during the emergence animation. Enable navigation/patrol, hitboxes, and attacks only after the enemy reaches a readable ready state.
- Give the player enough reaction time after the visual/audio tell. Start near 0.8 to 1.25 seconds and tune through playtesting rather than treating this as a fixed final number.
- Prevent duplicate activation. A grave cannot spawn a second enemy while its first activation is still active or already completed unless the encounter design explicitly resets on player death.
- Connect spawned enemies to the existing HUD enemy count. Decide consistently whether the count represents active enemies or remaining enemies, then preserve that meaning across the whole level.
- When the player dies or reloads a checkpoint, restore graves, triggers, defeated enemies, and the HUD counter according to the project's established checkpoint policy. Never leave a half-emerged enemy or stale count.
- Do not allow enemies to spawn inside terrain, the player, another enemy, or a decorative collision shape.

Encounter pacing

- Tutorial grave: one enemy, generous space, no simultaneous hazard.
- Second encounter: two staggered enemies from separated graves; do not surround the player instantly.
- Main row: a controlled mixed wave of zombies and skeletons, released in sequence or capped concurrency.
- Final cemetery beat: the most demanding encounter, but still small enough that attack telegraphs and escape space remain readable.

Use the real enemy capabilities to tune counts. If zombies or skeletons do not currently exist as functional enemy scenes, inventory what is missing and implement the smallest project-consistent solution with existing art; do not import replacements.

6. Enemy roles

- Zombies should create slow, steady ground pressure and make the player reposition. Avoid excessive health or uninterruptible crowding.
- Skeletons should create faster or more tactical pressure based on their existing behavior. Do not grant new attacks unless necessary and consistent with the current game.
- Mix roles by spacing and timing. Do not stack multiple bodies in the same grave or spawn a full mob around the player.
- Keep every emergence and attack telegraph visible against the darker background.

7. Make the night dark, not blue

> **Art direction: neutral charcoal-black night, deep gray silhouettes, restrained cold undertones, and small warm lantern pools. The scene must no longer be dominated by a bright blue moon or blue screen wash.**

Apply the correction at the correct rendering layer after auditing the scene:

- Reduce the saturation and luminance of the moon/background. The moon may remain visible as a dim silhouette or soft desaturated disc, but it must not flood half the screen with pale blue.
- Shift global ambience toward near-black charcoal or extremely dark neutral navy. Do not solve the problem by placing an opaque black rectangle over the entire scene.
- Preserve warm yellow-green or amber lantern pools as local navigation cues, but reduce oversized cones and prevent them from flattening the scene.
- Keep foreground ground edges slightly separated from the background so jumps and walkable surfaces remain obvious.
- Keep the player silhouette, orange eyes, enemies, attack telegraphs, graves that are about to activate, checkpoints, and exit cues readable.
- Do not darken the HUD, text, hearts, life/power bars, pause menus, or subtitles. Apply world lighting below the CanvasLayer/UI where appropriate.
- Avoid pure black crush. Background details may be subtle, but the player must still distinguish graves, enemy silhouettes, platform edges, and hazards.

Starting palette targets for testing

Use these only as visual starting points, not mandatory hardcoded values: global ambience around #11151A to #171A1E; distant silhouettes around #0A0F14 to #111820; muted moon values around #38404A to #555B63 at low opacity; lantern cores around muted #B5A64A with small falloff. Tune on the actual monitor and scene.

Readability check

At gameplay zoom, the player must be able to identify the floor, the next safe direction, an emerging enemy, and an attack wind-up without relying on the HUD or trial-and-error. Darkness should create mood, not hidden damage.

8. Camera, collision, and composition

- Extend camera limits to cover the new cemetery while preventing the camera from showing empty space beyond the level bounds.
- Match visible ground with continuous collision. Remove seams, invisible walls, snag points, unsupported edges, and decorative collisions.
- Keep graves and background crosses decorative unless a specific object is intentionally solid. Use consistent collision for large coffins/crypts only when the player can clearly read them as blocking objects.
- Keep foreground objects from hiding the player or enemy telegraphs. Use z-index, y-sorting, or fade behavior consistent with the project.
- Make the extension work at the project's supported resolutions and aspect ratios. The endpoint and spawn triggers must not depend on one screenshot resolution.

9. Implementation sequence

1. Audit the story scene, assets, enemy architecture, rendering stack, checkpoints, and online/shared dependencies.
2. Back up safety through normal version-control awareness. Preserve unrelated user changes and do not reset the worktree.
3. Extend terrain and camera bounds from the current endpoint. Verify the seam before adding encounters.
4. Dress the cemetery using existing assets while keeping decorative layers non-collidable where appropriate.
5. Implement one grave emergence and validate its state transitions: dormant, telegraph, emerging, active, defeated, and reset.
6. Connect the spawned enemy to existing combat and enemy-count logic.
7. Expand to the full paced encounter sequence with concurrency limits and fair activation distances.
8. Correct the palette and moon/background lighting at the proper world-rendering layer, preserving UI and gameplay readability.
9. Add or adjust checkpoint/onward behavior using existing systems.
10. Run gameplay, reload, death/reset, resolution, collision, and regression checks. Fix all reproducible issues before reporting completion.

10. Required testing

Test in a playable build, not only by parsing scripts or opening scenes.

- Walk from the existing completed section across the exact continuation seam into the cemetery.
- Approach every trigger slowly, quickly, while jumping, and while retreating.
- Confirm enemies never activate before their graves are visible and never attack during emergence.
- Kill enemies in different orders and verify the HUD counter remains correct.
- Die during each phase: before trigger, during telegraph, during emergence, during combat, and after clearing a wave.
- Reload the scene/checkpoint repeatedly and confirm no duplicate spawns, orphaned enemies, stuck triggers, or stale graves.
- Check collision on every new ground seam, grave cluster, crypt/coffin landmark, and level boundary.
- Verify camera bounds and composition at all supported resolutions/aspect ratios available in the project.
- Verify the darker color grade does not affect UI and does not hide the player, enemy telegraphs, graves, ground edges, hazards, or route markers.
- Run regression checks on existing story content and confirm that online mode/shared resources were not changed.

11. Acceptance criteria

- The arrow-sign/locator endpoint now leads naturally into a cemetery continuation to the right.
- The old road remains playable and visually intact except for the minimal seam required to extend it.
- The cemetery has a clear threshold, grave rows, a strong crypt/coffin landmark, combat space, and an onward cue.
- At least one zombie encounter and one skeleton encounter originate from graves with visible emergence, using existing project assets and systems.
- No enemy appears instantly in an active attacking state, overlaps the player on spawn, or deals unavoidable emergence damage.
- Enemy counting, death, checkpoint reload, and scene reload behave consistently without duplicates or stale state.
- The level is visibly darker and more neutral. The bright blue cast and oversized blue moon dominance are removed or strongly reduced.
- Lanterns and carefully controlled contrast keep the route, ground, player, enemies, graves, and telegraphs readable.
- Collisions match visible terrain and do not create seams, traps, invisible walls, or decorative blockers.
- No external assets were added, no screenshot pixels were used as game content, and no machine-specific paths were introduced.
- Online mode and shared multiplayer behavior remain untouched and functional.
- The final report lists every changed file, the purpose of each change, tests run, results, known limitations, and explicit confirmation of online-mode isolation.

12. Final delivery format

When implementation is complete, return a concise report containing:

1. Summary of the cemetery extension, grave emergence system, enemy encounters, and palette correction.
2. Exact changed files with one-line reasons.
3. Test matrix and results, including death/reload and darkness/readability checks.
4. Any remaining limitations or asset constraints.
5. A direct statement confirming whether online/multiplayer files or shared resources changed.

Do not claim completion from code inspection alone. Completion requires a playable verification of the extended route and grave encounters.

END OF IMPLEMENTATION PROMPT
